[DETAILED EXPLANATION OF THE INVENTION]

5 [0001]

[Technical Field of the Invention]

This invention relates to polymers useful as the base resin in resist compositions suited for microfabrication and sulfonic acid esters useful as the starting monomers for the
10 polymers. It also relates to resist compositions, especially chemical amplification resist compositions comprising the polymers, and a patterning process using the same.

[0002]

15 [Prior Art]

In the drive for higher integration and operating speeds in LSI devices, the pattern rule is made drastically finer.

The rapid advance toward finer pattern rules is
20 grounded on the development of a projection lens with an increased NA, a resist material with improved performance, and exposure light of a shorter wavelength. To the demand for a resist material with a higher resolution and sensitivity, chemical amplification positive working resist
25 materials which are catalyzed by acids generated upon light exposure are effective. They now become predominant resist materials especially adapted for deep UV lithography (Patent Document 1, 2: JP-B 2-27660 and JP-A 63-27829).

[0003]

30 Also, the change-over from i-line (365 nm) to shorter wavelength KrF laser (248 nm) brought about a significant innovation. Resist materials adapted for KrF excimer lasers enjoyed early use on the 0.30 micron process, passed through the 0.25 micron rule, and currently entered the mass
35 production phase on the 0.18 micron rule. Engineers have started investigation on the 0.10 micron rule or less, with the trend toward a finer pattern rule being accelerated.

[0004]

For ArF laser (193 nm), it is expected to enable miniaturization of the design rule to 0.13 μm or less. Since conventionally used novolac resins and polyvinylphenol resins have very strong absorption in proximity to 193 nm, they cannot be used as the base resin for resists. To ensure transparency and dry etching resistance, some engineers investigated acrylic and alicyclic (typically cycloolefin) resins. (Patent Document 3-6: JP-A 9-73173, JP-A 10-10739, JP-A 9-230595 and WO 97/33198).

[0005]

With respect to F_2 laser (157 nm) which is expected to enable further miniaturization to 0.10 μm or less, more difficulty arises in insuring transparency because it was found that acrylic resins which are used as the base resin for ArF are not transmissive to light at all and those cycloolefin resins having carbonyl bonds have strong absorption. It was also found that poly(vinyl phenol) which is used as the base resin for KrF has a window for absorption in proximity to 160 nm, so the transmittance is somewhat improved, but far below the practical level.

[0006]

Since carbonyl groups and carbon-to-carbon double bonds have absorption in proximity to 157 nm as mentioned above, reducing the number of such units is contemplated to be one effective way for improving transmittance. It was recently found that the transmittance in the F_2 region is outstandingly improved by introducing fluorine atoms into base polymers.

[0007]

It was reported in SPIE 2001, Proceedings 4345-31, "Polymer design for 157 nm chemically amplified resists" (Non Patent Document 1) that in resist compositions comprising a copolymer of tert-butyl α -trifluoromethylacrylate with 5-(2-hydroxy-2,2-bistrifluoromethyl)ethyl-2-norbornene and

a copolymer of tert-butyl α -trifluoromethylacrylate with
4-(2-hydroxy-2,2-bistrifluoromethyl)methylstyrene, the
absorbance of the polymer at 157 nm is improved to about 3.
However, these resins are still insufficient in transparency
5 because it is believed that an absorbance of 2 or less is
necessary to form a rectangular pattern at a film thickness
of at least 2,000 Å through F₂ exposure.

[0008]

The inventor have been earnestly studied and found
10 that incorporating fluorinated vinyl sulfonate units into
the above-described α -trifluoromethylacrylate polymers
improves the transparency while maintaining the substrate
adhesion and developer affinity of the resins. These
systems still have an absorbance of approximately 2.

[Problem to be Solved by the Invention]

The present invention has been done in view of the
35 above circumstances. An object of the invention is to
provide a novel polymer having a high transmittance to
vacuum ultraviolet radiation of up to 300 nm, especially F₂

(157 nm), Kr₂ (146 nm), KrAr (134 nm) and Ar₂ (126 nm) laser beams, and useful as the base resin in a resist composition, and a novel sulfonic acid ester useful as the starting monomer for the polymer. Another object is to provide a

[0011]

[Means for Solving the Problem and Embodiment of the
10 Invention]

15 side chain is used as a base resin, the resulting resist composition, especially chemically amplified resist composition is drastically improved in contrast and adhesion without detracting from transparency. Thus, the present invention has been completed.

Claim 15: The pattern forming process of claim 14 wherein

20 the high-energy radiation is an F₂ laser beam, Ar₂ laser beam or soft x-ray.

[0013]

The following is the detailed description of the present invention.

25 The inventors have found that for improving the transmittance in proximity to 157 nm, reducing the number of carbonyl groups and/or carbon-to-carbon double bonds is contemplated to be one effective way. It was also found that introducing fluorine atoms into base polymers makes a

30 great contribution to improved transmittance. In fact, poly(vinyl phenol) having fluorine introduced in its aromatic rings offers a transmittance nearly on a practically acceptable level (Patent Document 7: JP-A 2001-146505). However, this base polymer was found to turn

35 to be negative upon exposure to high-energy radiation as from an F₂ laser, interfering with its use as a practical resist. On the other hand, those polymers obtained by

introducing fluorine into acrylic resins or polymers containing in their backbone an alicyclic compound originating from a norbornene derivative were found to have a high transparency and eliminate the negative turning problem. However, an increased rate of introduction of fluorine into a resin to enhance the transparency thereof tends to compromise the adhesion of resin to substrate or the penetration of a developer.

[0014]

It has been found that sulfonates have a relatively high transmittance at about 157 nm despite two sulfur-oxygen double bonds, and a resin comprising such sulfonate units is dramatically improved in substrate adhesion and developer penetration as compared with the aforementioned fluorinated polymers. Specifically, in the present invention, using a base polymer comprising units of the general formula (2) derived from a sulfonate compound of the general formula (1) which is obtained by introducing fluorine into a tertiary alkyl ester of sulfonic acid which inherently lacks stability, a resist composition having an acid eliminating ability is obtained while maintaining stability.

[0016]

While the polymer or high molecular weight compound of the invention is defined as comprising recurring units of the general formula (2), recurring units of at least one type selected from the general formulae (3a) to (3f) and/or recurring units of the general formula (4) and/or recurring units of the general formula (5) and/or recurring units of the general formula (6) are preferably incorporated in order to improve the dissolution contrast, substrate adhesion, dry etching resistance and other properties of the resist.

[0054]

The polymers of the invention are generally synthesized by dissolving monomers corresponding to the
15 respective units of formulae (2), (3a) to (3f), (4), (4a), (4b), (5), (5a), (5b) and (6) and optionally, an adhesion-improving monomer, a transparency-improving monomer and the like in a solvent, adding a catalyst thereto, and effecting polymerization reaction while heating or cooling
20 the system if necessary. The polymerization reaction depends on the type of initiator or catalyst, trigger means (including light, heat, radiation and plasma), and polymerization conditions (including temperature, pressure, concentration, solvent, and additives). Commonly used for
25 preparation of the polymers of the invention are radical copolymerization of triggering polymerization with initiators such as 2,2'-azobisisobutyronitrile (AIBN) or the like, and ion (anion) polymerization using catalysts such as alkyl lithium. These polymerization steps may be carried
30 out in their conventional manner.

[0055]

The radical polymerization initiator used herein is not critical. Exemplary initiators include azo compounds such as AIBN, 2,2'-azobis(4-methoxy-2,4-dimethylvaleronitrile),
35 2,2'-azobis(2,4-dimethylvaleronitrile), and 2,2'-azobis(2,4,4-trimethylpentane); peroxide compounds such

as tert-butyl peroxyvalate, lauroyl peroxide, benzoyl peroxide and tert-butyl peroxyaurate; water-soluble initiators, for example, persulfate salts such as potassium persulfate; and redox combinations of potassium persulfate or peroxides such as hydrogen peroxide with reducing agents such as sodium sulfite. The amount of the polymerization initiator used is determined as appropriate in accordance with such factors as the identity of initiator and polymerization conditions, although the amount is often in the range of 0.001 to 5% by weight, especially 0.01 to 2% by weight based on the total weight of monomers to be polymerized.

[0056]

For the polymerization reaction, a solvent may be used. The polymerization solvent used herein is preferably one which does not interfere with the polymerization reaction. Typical solvents include ester solvents such as ethyl acetate and n-butyl acetate, ketone solvents such as acetone, methyl ethyl ketone and methyl isobutyl ketone, aliphatic or aromatic hydrocarbon solvents such as toluene, xylene and cyclohexane, alcohol solvents such as isopropyl alcohol and ethylene glycol monomethyl ether, and ether solvents such as diethyl ether, dioxane, and tetrahydrofuran. These solvents may be used alone or in admixture of two or more. Further, any of well-known molecular weight modifiers such as dodecylmercaptan may be used in the polymerization system.

[0057]

The temperature of polymerization reaction varies in accordance with the identity of polymerization initiator and the boiling point of the solvent although it is often preferably in the range of 20 to 200°C, and especially 50 to 140°C. Any desired reactor or vessel may be used for the polymerization reaction.

[0058]

From the solution or dispersion of the polymer thus obtained, the organic solvent or water serving as the

reaction medium is removed by any of well-known techniques. Suitable techniques include, for example, re-precipitation followed by filtration, and heat distillation under vacuum.

[0059]

5 Desirably the polymer has a weight average molecular weight of 1,000 to 500,000, and especially 2,000 to 100,000.

[0060]

The polymer of the invention can be used as a base resin in resist compositions, specifically chemical
10 amplification type resist compositions, and especially chemical amplification type positive working resist compositions. It is understood that the polymer of the invention may be admixed with another polymer for the purpose of altering the dynamic properties, thermal
15 properties, alkali solubility and other physical properties of polymer film. The type of the other polymer which can be admixed is not critical. Any of polymers known to be useful in resist use may be admixed in any desired proportion.

[0061]

[0062]

[Formula 35]

[0083]

These photoacid generators may be used singly or in combinations of two or more thereof. Onium salts are effective for improving rectangularity, while diazomethane
30 derivatives and glyoxime derivatives are effective for reducing standing waves. The combination of an onium salt with a diazomethane or a glyoxime derivative allows for fine adjustment of the profile.

[0084]

35 The photoacid generator is added in an amount of 0.1 to 50 parts, and especially 0.5 to 40 parts by weight, per 100 parts by weight of the base resin (all parts are by

weight, hereinafter). Less than 0.1 part of the photoacid generator may generate a less amount of acid upon exposure, sometimes leading to a poor sensitivity and resolution whereas more than 50 parts of the photoacid generator may
5 adversely affect transmittance and resolution.

[0085]

The basic compound used as component (D) is preferably a compound capable of suppressing the rate of diffusion when the acid generated by the photoacid generator diffuses
10 within the resist film. The inclusion of this type of basic compound holds down the rate of acid diffusion within the resist film, resulting in better resolution. In addition, it suppresses changes in sensitivity following exposure, thus reducing substrate and environment dependence, as well
15 as improving the exposure latitude and the pattern profile.

The basic compound is preferably formulated in an
10 amount of 0.001 to 2 parts, and especially 0.01 to 1 part by
weight, per 100 parts by weight of the base resin. Less
than 0.001 part of the basic compound may fail to achieve
the desired effects thereof, while the use of more than 2
parts would result in too low a sensitivity.

[0103]

The compounds serving as dissolution inhibitor have a
weight average molecular weight of 100 to 1,000, preferably
30 150 to 800.

An appropriate amount of the dissolution inhibitor is
0 to 50 parts, preferably 5 to 50 parts, and especially 10
to 30 parts by weight per 100 parts by weight of the base
resin. Less amounts of the dissolution inhibitor may fail
35 to yield an improved resolution, whereas too much amounts
would lead to slimming of the patterned film, and thus a

decline in resolution. The inhibitor may be used singly or as a mixture of two or more thereof.

[0104]

The resist composition of the invention may include optional ingredients, typically a surfactant which is commonly used for improving the coating characteristics. Optional ingredients may be added in conventional amounts so long as this does not compromise the objects of the invention.

10 [0105]

Illustrative, non-limiting, examples of the surfactant include nonionic surfactants, for example, polyoxyethylene alkyl ethers such as polyoxyethylene lauryl ether, polyoxyethylene stearyl ether, polyoxyethylene cetyl ether, 15 and polyoxyethylene oleyl ether, polyoxyethylene alkylaryl ethers such as polyoxyethylene octylphenol ether and polyoxyethylene nonylphenol ether, polyoxyethylene polyoxypropylene block copolymers, sorbitan fatty acid esters such as sorbitan monolaurate, sorbitan monopalmitate, 20 and sorbitan monostearate, and polyoxyethylene sorbitan fatty acid esters such as polyoxyethylene sorbitan monolaurate, polyoxyethylene sorbitan monopalmitate, polyoxyethylene sorbitan monostearate, polyoxyethylene sorbitan trioleate, and polyoxyethylene sorbitan 25 tristearate; fluorochemical surfactants such as EFTOP EF301, EF303 and EF352 (Tohkem Products Co., Ltd.), Megaface F171, F172 and F173 (Dai-Nippon Ink & Chemicals, Inc.), Fluorad FC430 and FC431 (Sumitomo 3M Co., Ltd.), Asahiguard AG710, Surflon S-381, S-382, SC101, SC102, SC103, SC104, SC105, 30 SC106, Surfynol E1004, KH-10, KH-20, KH-30 and KH-40 (Asahi Glass Co., Ltd.); organosiloxane polymers KP341, X-70-092 and X-70-093 (Shin-Etsu Chemical Co., Ltd.), acrylic acid or methacrylic acid Polyflow No. 75 and No. 95 (Kyo-eisha Ushi Kagaku Kogyo Co., Ltd.). Inter alia, FC430, Surflon S-381, 35 Surfynol E1004, KH-20 and KH-30 are preferred. These surfactants may be used alone or in admixture.

[0106]

Pattern formation using the resist composition of the invention may be carried out by a known lithographic technique. For example, the resist composition may be applied onto a substrate such as a silicon wafer by spin coating or the like to form a resist film having a thickness of 0.1 to 1.0 μm , which is then pre-baked on a hot plate at 60 to 200°C for 10 seconds to 10 minutes, and preferably at 80 to 150°C for 1/2 to 5 minutes. A patterning mask having the desired pattern may then be placed over the resist film, and the film exposed through the mask to an electron beam or to high-energy radiation such as deep-UV rays, excimer laser beams, or x-rays in a dose of about 1 to 200 mJ/cm^2 , and preferably about 10 to 100 mJ/cm^2 , then post-exposure baked (PEB) on a hot plate at 60 to 150°C for 10 seconds to 5 minutes, and preferably at 80 to 130°C for 1/2 to 3 minutes. Finally, development may be carried out using as the developer an aqueous alkali solution, such as 0.1 to 5%, and preferably 2 to 3%, tetramethylammonium hydroxide (TMAH), this being done by a conventional method such as dipping, puddling, or spraying for a period of 10 seconds to 3 minutes, and preferably 30 seconds to 2 minutes. These steps result in the formation of the desired pattern on the substrate.

[0107]

Of the various types of high-energy radiation that may be used, the resist composition of the invention is best suited to micro-pattern formation with, in particular, deep-UV rays having a wavelength of 254 to 120 nm, an excimer laser, especially ArF laser (193 nm), F_2 laser (157 nm), Kr_2 laser (146 nm), KrAr laser (134 nm) or Ar_2 laser (126 nm), x-rays, or an electron beam. Recommended is exposure to high-energy radiation in a wavelength band of 100 to 180 nm or 1 to 30 nm, specifically F_2 laser beam, Ar_2 laser beam or soft x-ray. The desired pattern may not be obtainable outside the upper and lower limits of the above range.

[0108]

[Effect of the Invention]

The resist composition of the invention is sensitive to high-energy radiation, maintains high transparency at a wavelength of up to 200 nm, and has improved alkali dissolution contrast and plasma etching resistance. These features permit the inventive resist composition to easily form a finely defined pattern having sidewalls perpendicular to the substrate and a high aspect ratio through F₂ laser exposure, making the resist ideal as a micropatterning material in VLSI fabrication.

5 [Evaluation]

Polymer transmittance measurement

Each polymer, 1 g, was thoroughly dissolved in 20 g of propylene glycol monomethyl ether acetate (PGMEA for propylene glycol monomethyl ether acetate, hereinafter), and
10 passed through a 0.2- μ m filter, obtaining a polymer solution.

[0130]

Comparative Polymer 1 is a monodisperse polyhydroxystyrene having a molecular weight of 10,000 and a dispersity (Mw/Mn) of 1.1 in which 30% of hydroxyl groups
15 are replaced by tetrahydropyranyl groups. Similarly, Comparative Polymer 2 is polymethyl methacrylate having a molecular weight of 15,000 and a dispersity (Mw/Mn) of 1.7; and Comparative Polymer 3 is a novolac polymer having a meta/para ratio of 40/60, a molecular weight of 9,000 and a
20 dispersity (Mw/Mn) of 2.5. The polymer solution is obtained from the above-described same procedure.

[0131]

The polymer solution was spin coated onto a MgF₂ substrate and baked on a hot plate at 100°C for 90 seconds,
25 forming a polymer film of 100 nm thick on the substrate. Using a vacuum ultraviolet spectrometer (VUV-200S by Nihon Bunko Co., Ltd.), the polymer film was measured for transmittance at 248 nm, 193 nm and 157 nm. The results are shown in Table 1. It is evident from Table 1 that resist
30 materials using the inventive polymers maintain sufficient transparency at the F₂ laser wavelength (157 nm).

5 Resist preparation and exposure

Resist solutions were prepared in a conventional manner by dissolving amounts as shown in Table 2 of the polymer, photoacid generator, basic compound, and dissolution inhibitor in 1,000 parts of PGMEA.

10 On silicon wafers having a film of DUV-30 (Brewer Science) coated to a thickness of 85 nm, the resist solutions were spin coated, then baked on a hot plate at 120°C for 90 seconds to give resist films having a thickness of 100 nm.

15 [0134]

The resist films were exposed by means of an F₂ excimer laser exposure tool (VUVES-4500 by Litho Tech Japan Corp.) while varying the exposure dose. Immediately after exposure, the resist films were baked (PEB) at 120°C for 90
20 seconds and then developed for 60 seconds with a 2.38% aqueous solution of tetramethylammonium hydroxide. The film

thickness was measured in different dose areas. From the residual film thickness-to-dose relationship, the sensitivity (E_{th}) was determined as the exposure dose giving a film thickness 0. A γ value which was the slope ($\tan\theta$) of the characteristic curve was also determined.

[0135]

Separately, through a mask having a Cr pattern formed on a MgF_2 substrate, the resist film in close contact with the Cr pattern surface was exposed to a F_2 laser for effecting contact exposure. The exposure was followed by similar PEB and development, forming a pattern. A cross section of the pattern was observed under SEM, the ascertainable minimum pattern size giving a resolution.

Upon exposure to VUVES, the resist compositions within the scope of the invention exhibited high gamma values and high contrast and exerted the positive working effect that the film thickness decreased with an increasing exposure dose. The resolving power upon contact exposure was high.

Dry etching test

A polymer solution was prepared by thoroughly dissolving 2 g in 10 g of PGMEA and passing the solution through a 0.2-micron size filter. The polymer solution was spin coated to a silicon substrate and baked to form a polymer film of 300 nm thick. The wafer having the polymer film formed thereon was subjected to dry etching under two sets of conditions. A first etching test with CHF_3/CF_4 gas was performed using a dry etching instrument TE-8500P by Tokyo Electron K.K. A second etching test with Cl_2/BCl_3 gas was performed using a dry etching instrument L-507D-L by Nichiden Anerba K.K. A difference in polymer film thickness before and after the etching test was determined. The etching conditions are shown in Table 3, and the results in Table 4.

It is evident from Table 4 that the resist compositions within the scope of the invention are fully resistant to dry etching.

[ABSTRACT]

[Means for Solution]

A sulfonate compound having the formula (1):

5 [Formula 1]

wherein R^1 to R^3 each are hydrogen, fluorine, or alkyl or fluorinated alkyl group, at least one of R^1 to R^3 contains fluorine.

[Effect]

10 The resist composition of the invention is sensitive to high-energy radiation, maintains high transparency at a wavelength of up to 200 nm, and has improved alkali dissolution contrast and plasma etching resistance.
